Sample Breakdown of a 1996 AP Chem FRQ (Hypothetical Example)

Let's consider a hypothetical example inspired by the types of questions from 1996: Question: An experiment involves heating a sample of solid sodium hydroxide and measuring the heat released when it dissolves in water. Given the data, calculate the enthalpy change per mole of NaOH dissolved and explain whether the process is exothermic or endothermic. Approach:

Step 1: Identify Known Data

- Mass of NaOH sample - Temperature change (ΔT) - Specific heat capacity of water - Final volume of solution

Step 2: Calculate Heat Absorbed or Released (q)

- Use the calorimetry formula: $q = mc\Delta T$ where m = mass of water, c = specific heat capacity, ΔT = temperature change

Step 3: Convert to Moles of NaOH

- Calculate moles of NaOH using molar mass $\text{moles} = \text{mass of NaOH} / \text{molar mass}$

Step 4: Determine Enthalpy Change per Mole

- $\Delta H = q / \text{moles}$

Step 5: Interpret the Results

- If q is negative, the process releases heat (exothermic) - If q is positive, it absorbs heat (endothermic)

Sample Calculation: - Suppose 5.00 g of NaOH dissolves, $\Delta T = 10^\circ\text{C}$, 100 g of water, $c = 4.18 \text{ J/g}\cdot^\circ\text{C}$ - $q = (100$

$g)(4.18 \text{ J/g}\cdot^{\circ}\text{C})(10^{\circ}\text{C}) = 4180 \text{ J}$ - Moles of NaOH = $5.00 \text{ g} / 40.00 \text{ g/mol} = 0.125 \text{ mol}$ - $\Delta H = 4180 \text{ J} / 0.125 \text{ mol} = 33,440 \text{ J/mol}$ or 33.44 kJ/mol Conclusion: Since heat is released, the dissolution process is exothermic, with an enthalpy change of approximately -33.44 kJ/mol .
