Sample CCNA Questions and In-Depth Explanations

To illustrate the depth and scope of CCNA exam questions, below are some representative examples along with detailed explanations.

Question 1: Understanding IP Addressing
Q: Which of the following IPv4 addresses is valid for assigning to a host device?
a) 192.168.1.0 b) 10.0.0.255 c) 172.16.255.255 d) 255.255.255.255
Answer: c) 172.16.255.255
Explanation: Valid host addresses must be within the network range and not be network or broadcast addresses. - 192.168.1.0 is a network address (assuming subnet mask 255.255.255.0). - 10.0.0.255 is a

broadcast address for the 10.0.0.0/8 network. - 172.16.255.255 is a valid broadcast address for the network 172.16.0.0/16, but as a host address, it's typically assigned as a broadcast address, so in practical use, it would not be assigned to a host. - 255.255.255.255 is the limited broadcast address, not assignable to hosts. In practice, the key learning point is recognizing valid host addresses and understanding subnetting rules.

Question 2: Routing Protocols Q: Which routing protocol is characterized by its link-state nature and uses a shortest path first algorithm? a) OSPF b) RIP c) EIGRP d) BGP Answer: a) OSPF Explanation: Open Shortest Path First (OSPF) is a link-state routing protocol that maintains a map of the network topology and computes the shortest path to each destination using Dijkstra's algorithm. - RIP uses distance-vector algorithms, relying on hop count. - EIGRP is a hybrid routing protocol using features of both distance-vector and link-state, but it is primarily classified as an enhanced distance-vector protocol. - BGP (Border Gateway Protocol) is an inter-autonomous system routing protocol based on path vector principles. Understanding protocol types and their characteristics is fundamental for network design and troubleshooting.

Question 3: VLAN Configuration Q: Which command is used to create a new VLAN on a Cisco switch? a) vlan 10 b) switchport vlan 10 c) create vlan 10 d) vlan database Answer: a) vlan 10 Explanation: On Cisco switches, to create a VLAN, you enter global configuration mode and specify the VLAN number with the `vlan` command: Switch(config) vlan 10 Switch(config-vlan) name Sales Switch(config-vlan) exit The command `vlan 10` initializes the VLAN configuration mode, allowing you to assign a name and configure other parameters. - The `switchport vlan` command is used on interface configuration mode to assign an interface to a VLAN. - The `create vlan 10` command is not valid in Cisco IOS. - The `vlan database` command was used in older IOS versions but is now deprecated. Knowledge of VLAN configuration is crucial for network segmentation and security.

Question 4: Security Fundamentals Q: Which protocol is commonly used to secure remote access to network devices? a) Telnet b) SSH c) HTTP d) FTP Answer: b) SSH Explanation: Secure Shell (SSH) encrypts data transmitted over the network, providing secure remote management of devices. - Telnet transmits data in plaintext, making it insecure. - HTTP is used for web traffic, not remote device management. - FTP is used for file transfer, not device access. Implementing SSH is a best practice to prevent eavesdropping and unauthorized access.

Question 5: Automation and Programmability Q: Which feature allows network devices to be managed programmatically via APIs? a) SNMP b) REST API c) Telnet d) Spanning Tree Protocol Answer: b) REST API Explanation: REST APIs enable network devices to be managed and automated through standardized HTTP requests, supporting modern network automation tools. - SNMP is used for network monitoring and management but is not inherently API-based. - Telnet is a legacy protocol for remote access, not automation. - Spanning Tree Protocol prevents loops in Layer 2 networks; it is unrelated to programmability. Understanding automation protocols and APIs is essential for modern network operations.
